

Instrumentation and Performance Analysis of Distributed Systems with Freud

Stefano Taillefert

Advisor: prof. Antonio Carzaniga

Project description

[Freud](#) is a software performance analysis tool that derives performance annotations from measurements of running systems. The goal of this project is to extend Freud to instrument and collect data from a *distributed* software system. This means augmenting the existing implementation to be able to link the data collected over distributed components using causal relations.

Task list

- Develop a simple distributed application based on an RPC library to be used as an initial test bench
- Develop an instrumentation for both client side, server side, and – crucially – the RPC library
- Design a method to save and retrieve measurement logs from all the remote components
- Design an algorithm to merge the logs from all the systems into a single coherent trace
- Integrate the trace in the existing statistics tool (`freud-statistics`) to derive the performance annotations
- Identify and analyze some third-party, non-trivial distributed applications
- Write the report and prepare the poster and presentation
- Pizza
